Do people really believe the misleading information that new treatments render early detection unnecessary as Drs. Kalager and Miller wants you to believe? The facts clear the issue: follow-up of 9040 patients with breast cancers diagnosed between 1998–2003 showed that even in the era of adjuvant systemic therapy, node-negative cancers still have considerably better survival than node positive. While survival of women with node-positive tumors has improved in the era of adjuvant systemic therapy compared with earlier times, it clearly is a worthy goal to have the cancer diagnosed before it spreads to the lymph nodes. Screen detected node positive cases had a better survival than clinically detected node negative cases. Thus, improvements in therapy have not rendered early detection redundant.
